

Automation Blueprint

Read this last, and build it later.

Automating a process you haven't run by hand produces a machine that does the wrong thing quickly. Run twenty accounts manually first. You'll discover what actually takes time, and it usually isn't what you expected.

When you're ready, this is the architecture.

The pipeline

Account source → Enrichment → Verification → Trigger detection → Scoring
→ HUMAN REVIEW → Outreach → Replies → Records → Follow-up → Reporting

Nine of those ten steps can be automated. The one in capitals cannot, and the value of the whole thing depends on that.

What to automate, what to keep

Step	Automate?	Why
Finding accounts	Yes	Mechanical. Search, pull, save.
Filtering out obvious misfits	Yes	Rules-based. No website, wrong area, too small.
Finding contact details	Yes, partly	Machines find addresses well. Deciding who signs is judgment.
Verifying an email is real	Yes	Purely mechanical, and it protects your domain.
Watching for triggers	Yes	The best use of automation here. Checking permits and listings weekly by hand is tedious and easy to skip.
Scoring	Yes	It's arithmetic.
Deciding who to contact	No	See below.
Approving the send	No	See below.
Sending an approved batch	Yes	Once a human approved that batch.
Sorting replies by type	Yes, partly	Sorting is fine. Answering is not.
Replying to a person	No	

Step	Automate?	Why
Suppressing an opt-out	Yes, always	Should be instant and not depend on you noticing.
Logging activity	Yes	
Reminding you a follow-up is due	Yes	
Weekly reporting	Yes	

The three that must stay human

Deciding who to contact. A machine can score an account. It can't tell you that the building is across the road from your worst customer, or that you met the owner and it went badly. Look at the list before it becomes a send.

Approving the send. Every batch, every time. Not "approved for the week." The failure this prevents is the expensive one: a merge field that didn't populate, a stale trigger, an account that should have been suppressed. All three are obvious to a person glancing at the batch and invisible to the system that produced it.

Replying to a person. Someone who replies to a cold email is the scarcest thing this system produces. An automated answer squanders it, and they can tell.

Never automate

- Sending without a human looking at that specific batch
- Any claim about a prospect the system inferred rather than observed
- Re-adding someone who opted out, for any reason, ever
- Automated calling, recorded messages, or synthetic voice — a separate area of law, and the wrong place to experiment
- Changing a price

The gates

Build these as hard stops. A gate that warns and continues isn't a gate.

Gate	Checks	Blocks when
Suppression	Every address and number against your opt-out list, at the moment of sending	Any match
Verification	Address confirmed deliverable, recently	Unverified, or checked over 90 days ago
Score floor	Total score	Below 8

Gate	Checks	Blocks when
Trigger validity	Source and date present, still inside its window	Missing or expired
Claim check	The actual merged text, not the template	Any sentence asserts something not in the trigger record
Compliance	Business name, postal address, opt-out present	Any missing
Volume	Daily send count against what your domain can carry	Over the limit
Human approval	A person approved <i>this</i> batch	Always required
Kill switch	A single flag that stops all sending	When set

Check suppression at send time, not when the list was built. A list built Monday and sent Thursday can email someone who opted out on Tuesday.

The claim check is the one no tool does for you. Read the merged emails — five of them, not the template — and confirm every statement about the recipient traces to something dated in your records.

Build it in this order

Stop at whatever level is genuinely helping. Most operators never need level 4.

Level 0 — manual. Spreadsheet and inbox. Do this for at least twenty accounts.

Level 1 — save time on finding. Automate account discovery and contact extraction into your tracker. Everything downstream stays manual. Biggest time saving for the least risk, and it's where most people should stop for the first month.

Level 2 — add trigger watching. Weekly automated checks against permit portals, listings and job boards, writing into the Trigger Tracker. This is the highest-value automation in the system, because trigger hunting is the step people skip when busy — and it's the step the whole method depends on.

Level 3 — sequencing with an approval gate. Sending tool holds the sequences; you approve each batch. Replies route back to your tracker.

Level 4 — full orchestration. One workflow end to end, with the human gate still in the middle. Only worth it above a few hundred accounts a month.

Tool options

None of these is required. The method works on a spreadsheet.

Job	Options	Notes
Account discovery	Apify Google Maps scrapers, Outscraper, manual search	Apify charges per result, typically a few dollars per thousand. Pricing changes — check before committing.
Contact enrichment	Apollo, Hunter, Clearbit, or reading their website	For small local businesses, their own site is often better than a database. Databases tend to return generic inboxes.
Email verification	NeverBounce, ZeroBounce, Bouncer	Cheap. Do not skip it.
Trigger sources	County permit portals, Google Business listings, Indeed, state registries, CRE listing sites	Mostly free and public.
Orchestration	n8n, Make, Zapier, or a scheduled script	n8n self-hosts, which matters if you're storing contact data.
Storage	The provided tracker, Google Sheets, Airtable, or a CRM	Move off the spreadsheet when it starts hurting, not before.
Sending	Your normal email, or a sequencing tool	Sequencing tools help at volume and are unnecessary below about fifty a week.

One warning on sequencing tools: merge-field syntax differs between them. Some use `{{first_name}}`, others `{{firstName}}`. Get it wrong and your prospects receive the literal tag. Send yourself a test before every new campaign.

How much can you actually send?

Less than you'd think, and the limit is your sender reputation rather than your software.

Four rules

Your mailbox has one daily budget, and warmup spends from it. Most guidance quotes a cap per mailbox per day — the number people miss is that it covers *all* traffic, including the warmup emails your tool keeps sending in the background. If your cap is 45 and warmup uses 12, your real cold-email ceiling is 33. Plan against 45 and you're running at 125% of it.

Follow-ups count too. A three-email sequence to 100 people is up to 300 sends, not 100. When you're working out how many accounts you can handle a week, divide your send capacity by your average number of touches.

Spread mailboxes across domains. Two or three per domain, not all of them on one. If a domain's reputation goes bad you lose that slice, not everything. Ten domains with two or three mailboxes each is a more resilient setup than three domains with eight.

Ramp, don't start at the ceiling. A new mailbox sending at full volume on day one is the clearest possible signal that it isn't a person. Start low, hold each step for about a week, and only step up if bounces and complaints stay clean.

A workable ramp

Week	Cold emails per mailbox per day
1–3	0 — warmup only
4	20
5	25
6	30
7+	33, and don't rush past it

Hold a step if anything looks wrong. A bad week means staying where you are, not pushing through. Reputation takes weeks to build and days to lose.

For most operators, this is academic

If you're working thirty well-chosen accounts a month, you'll never approach these limits and you don't need sending software at all. These numbers matter when you're running hundreds a week — and if your reply rate is poor, more volume is the wrong fix anyway. Go back to which accounts you picked and whether the trigger was real.

A worked example — the trigger watcher

The one automation worth building early, even if you build nothing else.

Once a week, automatically:

1. Read the list of accounts in your tracker that are still active.
2. For each, check: has the Google listing address changed? Is there a new permit at that address?

Is there a new job posting mentioning facilities or operations?

3. Where something is found, write a row into the Trigger Tracker — the observation, the source, and the date.

4. Send yourself one summary email: *"4 new triggers this week."*

Then you open the tracker and decide what to do. The automation found the signals. It didn't decide anything, didn't contact anyone, and didn't interpret what it saw.

That division is the whole design. Machines are good at watching things constantly and bad at knowing what they mean. You are the other way round.

Before you automate anything

- You've run at least twenty accounts by hand

- You know which step actually eats your time
- Your suppression list exists and is one list, not several
- You can stop all sending with one switch
- Every automated write is logged, so you can see what happened
- The human approval gate is built in from the start, not added later

The last one matters most. An approval gate added to a working automation is a gate people learn to click through. Built in from the beginning, it's just how the system works.
